Introduction

• A conformal field theory (CFT) on \mathbb{R}^d is a quantum field theory with symmetry group

[Picture from Eftychia '18]

- A CFT can be defined by a list $\{\mathcal{O}_i, \{\Delta_i, \lambda_{ij}^k\}\}$.
- Solution strategies:
 - "Perturbative" methods (Large-N, ϵ -expansion...)
 - Consistency-based methods (Bootstrap, sum rules...)

The O(2) CFT in three dimensions

- Consider the O(2)-vector CFT on \mathbb{R}^3 (3d XY model, ⁴He superfluid...).
- Strongly coupled IR Wilson-Fischer fixed point of the ${\cal O}(2)$ scalar ϕ^4 theory.
- Scaling dimensions Δ_i are contained in the partition function on $S^1_\beta \times S^2$:

$$\mathcal{Z}_{S^{2}}(\beta) = \operatorname{Tr}\left\{e^{-\beta\hat{H}_{S^{2}}}\right\} = \sum_{i} e^{-\beta\Delta_{i}}$$
$$\mathcal{L}_{\mathrm{UV}} = (\partial\phi)^{2}$$
$$\mathcal{L}_{\mathrm{int}} = g(\Lambda) \phi^{4}$$
$$\mathcal{L}_{\mathrm{UV}} = (\partial\phi)^{2}$$

Large-charge expansion

Consider the partition function at fixed charge Q:

$$\mathcal{Z}_{S^2}(\beta, Q) = \operatorname{Tr}\left\{e^{-\beta \hat{H}_{S^2}}\delta(\hat{Q} - Q)\right\} = \sum_{Q_i = Q} e^{-\beta \Delta_i(Q)}$$

In the limit $Q \gg 1$ the partition function $\mathcal{Z}_{S^d}(\beta, Q)$ can be realised via an EFT of Goldstone bosons (GB) realising the symmetry breaking:

$$SO(d+1,1) \times O(2) \longrightarrow SO(d) \times D'$$

with natural cutoff $\Lambda \sim Q^{1/d}/r_{S^d}.$

This pattern can be realised in different ways:

- "Conformal superfluid" ⇒ Simplest option
- Fermi liquid
- More exotic possibilities...

[Hellerman, Orlando, Reffert, Watanabe '15] [Monin, Pirtskhalava, Rattazzi, Seibold '16]

The superfluid prediction

- D, Q broken, but the combination $D' = D + \mu Q$ is preserved.
- Low-energy modes for this pattern are described by the EFT:

$$\mathcal{L} = c_{3/2} (\partial_{\mu} \chi \partial^{\mu} \chi)^{\frac{3}{2}} + c_{1/2} (\partial_{\mu} \chi \partial^{\mu} \chi)^{\frac{1}{2}} R + \dots$$

• The spectrum contains a non-relativistic GB:

• In this realisation one finds the scaling dimension of the lowest Q-primary:

$$\Delta(Q) = \hat{c}_{3/2}Q^{\frac{3}{2}} + \hat{c}_{1/2}Q^{\frac{1}{2}} + \mathcal{O}(Q^{-\frac{1}{2}})$$

[Delacretaz, Endlich, Monin, Penco, Riva '14] [Gaumé, Orlando, Reffert '20 (review)]

Motivation for present work

$$\Delta(Q) = \hat{c}_{3/2}Q^{\frac{3}{2}} + \hat{c}_{1/2}Q^{\frac{1}{2}} + \# \left\{ \begin{matrix} Q^0 \\ \log Q \end{matrix} \right\} + \mathcal{O}(Q^{-\frac{1}{2}})$$

- Predictions in the non-perturbative sector ($e^{-Q^{\alpha}}$ vs. $Q^{0},\,\log Q...$).

[Hellerman et at. '15, Cuomo '20]

- Extrapolation to small charge operators $Q \sim \mathcal{O}(1)$.
- Explaining the effectiveness of $\Delta(Q)\sim Q^{\frac{3}{2}} \mbox{ at low }Q \mbox{ in MC data}.$

[[]Banerjee, Chandrasekharan, Orlando '17]

Extension to O(2N)

- Consider the extension to O(2N) at leading order in $N \gg 1$.
- Fix the charges $Q_{i=1...N}$ of $O(2)^N \subset O(2N)$ and consider the limit

$$Q \coloneqq \sum_{i=1}^{N} Q_i, \quad Q/N \gg 1$$

• At leading order in large-N one finds:

[Gaumé et al. '17, '19]

Large-order growth of $\Delta(Q)$

One expect instanton-type contributions of the order $\sim e^{-\#\sqrt{Q}}.$

Resurgence and transseries

Employ a transseries ansatz: $\Delta(Q) \xrightarrow[Q \to \infty]{} \Xi(\sigma_k, Q)$

[Ecalle'81 ... Dorigoni '14 (review)]

Grand canonical picture

Heat kernel trace on $\overline{S^2}$

$$|y|e^{-t\Delta_{S^2}}|x\rangle\simeq$$

(I) Has a small-t asymptotic expansion:

$$\operatorname{Tr}\left\{e^{\left(\Delta_{S^2}-\frac{1}{4}\right)t}\right\} \xrightarrow[t\to 0]{} \frac{1}{t}\sum_{n=0}^{\infty}(-1)^{n+1}(1-2^{1-2n})\frac{B_{2n}}{n!}t^n$$

(II) The Borel transform is particularly simple:

$$\mathcal{B}(\zeta) = \frac{1}{\sqrt{\pi}} \frac{\zeta}{\sin \zeta} \xrightarrow{-3\pi - 2\pi - \pi} \xrightarrow{-\pi} \xrightarrow{0^+} \xrightarrow{0^+} \xrightarrow{0^-} \xrightarrow{0$$

Prediction for non-perturbative contributions

• The Heat Kernel has a a Borel summation of the form

$$\begin{aligned} \mathcal{S}_{\pm}(\sigma_{k}^{\pm},t) = & \frac{2}{\sqrt{\pi}t^{\frac{3}{2}}} \int_{0}^{e^{i0^{\pm}\infty}} \mathrm{d}\zeta \, e^{-\zeta^{2}/t} \left(\frac{\zeta}{\sin\zeta}\right) \\ &+ 2i \left(\frac{\pi}{t}\right)^{\frac{3}{2}} \sum_{k \neq 0} \sigma_{k}^{\pm} (-1)^{k+1} |k| \, e^{-\frac{\pi^{2}k^{2}}{t}} \end{aligned}$$

• The leading non-perturbative correction are of the form:

$$\Delta(Q) \supset e^{-2\pi|k|\sqrt{\frac{Q}{2N}}}, \quad k \in \mathbb{Z}$$

- These contributions are of order $\sim 10^{-2}$ at Q = 1. Compatible with MC result (first 3 terms fit with relative error within 10^{-2}).
- What about the constants σ_k ?

Heat Kernel as a Worldline path integral

[Strassler '92, Schubert '96 (review) ... Bastianelli '05]

Expectation: saddle-point approximation around closed S^2 geodesics.

... Are these stable saddles?

Fluctuation modes on S^2

Summation of the grand potential

Comparing with the resurgence answer one can fix all ambiguities as

$$\sigma_k^{\pm} = \mp \frac{1}{2} \quad \forall k \in \mathbb{Z}$$

• The grand potential can be extrapolated to any (small) μ by

1

$$\mathcal{S}\{\omega\}(\mu) = \frac{1}{\pi} \left(\mu^2 - \frac{1}{4}\right) \text{P.V.} \int_0^\infty \frac{\mathrm{d}\zeta}{\zeta \sin\zeta} K_2\left(2\zeta \sqrt{\mu^2 - \frac{1}{4}}\right)$$

• This can be compared with the small- μ expansion:

$$|\omega_{\text{small}-\mu} - \omega_{\text{resurgence}}|(\mu = 0.65) \sim 10^{-11}$$

A glimpse of finite-N

- Under the assumptions:
 - $\circ \Delta(Q)$ has an asymptotic perturbative expansion for any N.
 - The leading singularity is determined via saddle of a WL integral for a particle with mass $m \sim \mu$ (Gapped goldstone? [Nicolis, Piazza '13])
- Together with scale invariance, this would lead to a prediction

$$\Delta(Q) \supset e^{-c(2\pi r_{S^2}) \times \Lambda}, \quad \Lambda \sim \sqrt{Q}/r_{S^2}$$

- Generalise $\Delta(Q)$ to a transseries of the form

$$\Delta(Q) = Q^{\frac{3}{2}} \sum_{n} \hat{c}_n Q^{-n} + e^{-c(2\pi)\sqrt{Q}} \left\{ Q^{\kappa} \sum_{n} \hat{c}_n^{(1)} Q^{-n/2} \right\} + \dots$$

... Work in progress!

Conclusions

In the the O(2N) Wilson-Fischer CFT at fixed charge(s) Q:

- The regime $Q/(2N) \gg 1$ is asymptotic, with factorial growth $\sim (n!)^2$.
- The factorial growth is driven by WL instantons which are (unstable) saddles of a QM path integral.
- The set of non-perturbative corrections depends only on the S^2 geometry, in particular the leading contributions are of the form $\Delta \supset e^{-2\pi |k|} \sqrt{Q/(2N)}$.

Thank you for your attention!
