

Protecting Lepton Flavour Universality

The role of gauged flavour symmetry

Master's Thesis at

Why this thesis?

- The Standard Model of particle physics is a very successful model: many experimental confirmations, good description of phenomena at energies currently accessible in accelerators.

- Clues we need to go beyond:

1. Experimental data not explained within the SM (ν masses, Dark Matter, baryon asymmetry...)
2. Experimental anomalies in indirect searches.

Anomalies in B-meson decays - observables of interest

- $b \rightarrow s\mu^+\mu^-$ branching ratios and angular observables (e.g. $B \rightarrow K^{(*)}\mu^+\mu^-$ and $B_s \rightarrow \phi\mu^+\mu^-$)
- The Lepton Flavour Universality ratios

$$R_{K^{(*)}} = \frac{BR[B \rightarrow K^{(*)}\mu^+\mu^-]}{BR[B \rightarrow K^{(*)}e^+e^-]}$$

1. Clean observables.
 2. SM prediction: $R_{K^{(*)}}^{SM} \approx 1$.
- $B_s \rightarrow \mu^+\mu^-$
 1. Another clean observable.
 2. Can distinguish between different NP scenarios.

Methodology:

theory input/bias

Our model: SM extension with a gauged flavour symmetry.

UV completion

Leptoquark models with $\mathcal{L}_{\text{int}} = \alpha Q \ell S$
Perform better: suppression of
 $|\Delta F| = 2$ and four-lepton processes.

simplified models

EFT

B-meson decays are described by the Weak Effective Theory (WET) Hamiltonian

$$\mathcal{H}_{\text{eff}} = \mathcal{H}_{\text{eff}}^{\text{SM}} - \frac{4G_F}{\sqrt{2}} \frac{e^2}{16\pi^2} \sum_{q=s,d} \sum_{\ell=e,\mu} \sum_{i=9,10,S,P} V_{tb} V_{tq}^* (C_i^{bq\ell\ell} O_i^{bq\ell\ell} + C_i'^{bq\ell\ell} O_i'^{bq\ell\ell}) + h.c.$$

$$O_9^{bs\ell\ell} = (\bar{b}\gamma_\mu P_L s)(\bar{\ell}\gamma^\mu \ell), \quad O_{10}^{bs\ell\ell} = (\bar{b}\gamma_\mu P_L s)(\bar{\ell}\gamma^\mu \gamma_5 \ell)$$

experimental input

The $SU(2)_\ell$ flavour symmetry

- Goal: build a UV completion of the SM.
- Main idea: if LFU must be preserved, it may be protected in the UV. How? A $SU(2)_\ell$ gauged flavour symmetry, acting on light lepton generations.
- NP scenario: $C_9^{bs\ell\ell} = -C_{10}^{bs\ell\ell}$, i.e. NP only coupled to left-handed leptons. Hence, we charge under the new symmetry $L = (l_1, l_2)^T \sim \mathbf{2}$.
- We add scalar LQs: we work with $S \sim (\bar{\mathbf{3}}, \mathbf{3})_{1/3}$ of G_{SM} .
- Symmetry not observed $\Rightarrow$ SSB mechanism at work. We postulate a scalar $\phi \sim \mathbf{2}$ of $SU(2)_\ell$ (SM-singlet) s.t. $\langle \phi \rangle = (0, v_\phi)^T$, hence $SU(2)_\ell \xrightarrow{\langle \phi \rangle} 1$.
- Other reasons to gauge this symmetry: we assign charge $S = (S_1, S_2)^T \sim \mathbf{2}$ of $SU(2)_\ell$. This prevents:
 1. LFV processes such as $\ell_i \rightarrow \ell_f \gamma$.
 2. Baryon number-violating interactions such as $\mathcal{L} = QQS$.

- Starting requirements:

1. **Anomaly-free gauge theory** → this requirement may predict a new light fermionic sector (not in our model).

2. $m_e \ll m_\mu \ll m_\tau$.

- Identify **mass eigenstates** of the theory: fundamental to explore the phenomenological implications of the model.

- At the renormalisable level the Yukawa sector is

$$-\mathcal{L}_{\text{Yuk}}^{D=4} = C_{12} L H E^c + C_3 l_3 H e_3^c + h.c. \Rightarrow M_l = v \begin{pmatrix} C_{12} \cdot 1_{2 \times 2} & 0 \\ 0 & C_3 \end{pmatrix}$$

- We must take into account radiative corrections, described by effective operators:

$$\mathcal{L}_{\text{Yuk}} = \mathcal{L}_{\text{Yuk}}^{D=4} + \mathcal{L}_{\text{Yuk}}^{D=5} \Rightarrow M_l = v \begin{pmatrix} C_{12} & 0 & \epsilon \tilde{C}_L \\ 0 & C_{12} & \epsilon C_L \\ \epsilon \tilde{C}_R & \epsilon C_R & C_3 \end{pmatrix}, \quad \epsilon = \frac{v_\phi}{\Lambda}$$

- If we admit $C_{12} \sim \epsilon_e \ll 1$, we find: $m_e \sim v \epsilon_e \ll m_\mu \sim \epsilon v \ll m_\tau \sim v$.

- The diagonalisation of M_l implies that the states corresponding to e, μ, τ are a mixing of the interaction eigenstates:

$$L = \begin{pmatrix} l_1 \\ l_2 \end{pmatrix} = \begin{pmatrix} (U_L)_{1\alpha} l_\alpha \\ (U_L)_{2\alpha} l_\alpha \end{pmatrix} \Rightarrow \mathcal{L}_{\text{int}} = \sum_{j=1,2} \sum_{\beta=e,\mu,\tau} (U_L)_{j\beta} \alpha_i \bar{Q}_i^{ca} \epsilon^{ab} (\sigma^k S_j^k)^{bd} l_\beta^d + h.c$$

- This introduces **correlations between different observables** that may be used in the future to **test/falsify** the model!

Conclusions

- In absence of signals in direct searches, flavour physics plays a key role, as it offers an insight into new physics through indirect searches.
- We identified possible new mediators of NP, i.e. Leptoquarks.
- We identified a possible process which might help to test our model.
- Many possible routes for **future studies**: a more thorough study of the scalar sector, the Landau pole of $G_{SM} \times SU(2)_\ell$, ν masses and oscillations, phenomenological comparison with a gauged $U(1)_{L_e-L_\mu}$ model.

My current focus: CFTs, defects and semiclassics

- CFTs characterised by the absence of running in the theory.
- Add impurity in space $\Rightarrow$ is it possible to define a Defect Conformal Field Theory (DCFT) in such a setting?
- Study of the phases Wilson Lines can have [O. Aharony, G. Cuomo, Z. Komargodski, M. Mezei, and A. Raviv-Moshe. *Phases of Wilson lines: conformality and screening*. JHEP, 12:183, 2023]
- Extension of the study to fermion-boson interacting theories.

- Employment of semiclassical methods for computation of CFT data to any loop order.
- E.g.: scaling dimension Δ_n of composite operators ϕ^n . [O. Antipin, J. Bersini, and F. Sannino. *Exact Results for Scaling Dimensions of Composite Operators in the ϕ^4 Theory*. 8 2024.]
- Next to come: NLO computations.

Thank you for your attention!
